Introduction Two years ago I came across Pearl's work on using directed cyclical graphs (DAGs) to model the problem of causal inference and have read the debate between academics on Pearl's framework vs Rubin's potential outcomes framework. Then I found it quite intriguing from a scientific methods and history perspective how two different formal frameworks could be developed to solve a ...

The causal pie model is a very simple model, perhaps the simplest, that captures the basic workings of causation. The model is instrumental in understanding a range of results, such as those discussed in this paper, and in avoiding common mistakes, such as partitions between nonmutually exclusive component causes and summing causes to 100%.

You write: "I want to prove AR(2) model is causal." Is simply not possible. AR and/or ARMA models are never causal. ARMA models was thought exactly for describing a process with its own past. These explicitly have merely statistical meaning. Causality is something the go beyond merely statistical relationship and involve more than one variable.

In philosophy of science, a causal model (or structural causal model) is a conceptual model that describes the causal mechanisms of a system. Causal models can improve study designs by providing clear rules for deciding which independent variables need to be included/controlled for.

1. Specify knowledge about the system to be studied using a causal model. Of the several models available, we focus on the structural causal model, 5-10 which provides a unification of the languages of counterfactuals, 11,12 structural equations, 13,14 and causal graphs. 1,7 Structural causal models provide a rigorous language for expressing both background knowledge and its limits.

The objective of this paper is to introduce the R package pcalg, explain the range of functions on simulated data sets and summarize some applications. To get started, we show how two of the main functions (one for causal structure learning and one for estimating causal effects from observational data) can be used in a typical application.

Causal models are mathematical models representing causal relationships within an individual system or population. They facilitate inferences about causal relationships from statistical data. They can teach us a good deal about the epistemology of causation, and about the relationship between causation and probability.
