Equihash Asymmetric Proof Of Work Based On The

Equihash is a memory-hard Proof-of-Work algorithm introduced by the University of Luxembourg's Interdisciplinary Centre for Security, Reliability and Trust at the 2016 Network and Distributed System Security Symposium. The algorithm is based on a generalization of the Birthday problem which finds colliding hash values. It has severe time-space trade-offs but concedes vulnerability to unforeseen parallel optimizations. It was designed such that parallel implementations are bottle-necked by memory

In this paper we solve this open problem and show how to construct an asymmetric proof-of-work (PoW) based on a computationally hard problem, which requires a lot of memory to generate a proof (called ”memory-hardness” feature) but is instant to verify.

Equihash: asymmetric proof-of-work based on the Generalized Birthday problem. [en] The proof-of-work is a central concept in modern cryptocurrencies, but the requirement for fast verification so far made it an easy prey for GPU-, ASIC-, and botnet-equipped users.

Equihash is the proof-of-work hash function in the Zcash and Bitcoin Gold blockchains. It is memory-intensive hash-function (requires a lot of RAM for fast calculation), so it is believed to be ASIC-resistant. How does Equihash work? Uses BLAKE2b to compute 50 MB hash dataset from the previous blocks in the blockchain (until the current block).
