Theory of a steam turbine Artwork: An early steam turbine design developed in 1888 by Swedish engineer Gustav de Laval (1845-1913). It works by directing straight-line jets of high-speed steam at a steel paddle wheel, with reasonable efficiency, so it's an example of an impulse turbine (explained below).

The book mainly describes Russian practises in designing and building steam turbines that was being followed during late 1950s and 1960s. The units used in the book are Metric (and not SI). The book describes both the theoretical principles and the construction details.

There are two classical types of turbine stage designs: the impulse stage and the reaction stage. Steam turbines can be noncondensing or condensing.

Principle of operation and design. An ideal steam turbine is considered to be an isentropic process, or constant entropy process, in which the entropy of the steam entering the turbine is equal to

the entropy of the steam leaving the turbine. No steam turbine is truly isentropic, however, with typical isentropic efficiencies ranging from 20-90% based on the application of the turbine.
